Explanation: In CMOS logic circuit, the switching operation occurs because N-MOS transistor turns ON, and p-MOS transistor turns OFF for input '1' and N-MOS transistor turns

OFF, and p-MOS transistor turns ON for input '0'. The networks are arranged such that one is ON and the other OFF for any input pattern.

The performance of digital circuits, opposed to analog, is relatively independent of actual component values in the implementing circuit.

Therefore, digital systems more reliably

reproduce the desired responses in spite of temperature variations or component aging. In addition, in digital circuits there is little need for component matching.
